

Virtual Try-On Model Evaluation - Assignment

Objective: Identify the best-performing virtual try-on AI model for production use, evaluated on accuracy, generation speed, and cost.

About Vizzle

Vizzle is building AI-powered virtual try-on experiences for fashion e-commerce, enabling shoppers to visualize how garments look on a model before purchasing. Selecting the right underlying try-on model is critical to product quality, user experience, and unit economics. This assignment is designed to identify the most accurate, fastest, and most cost-efficient virtual try-on model available today.

Assignment Objective

Research and test virtual try-on (VTON) models/APIs available in the market, and identify the model(s) that deliver the best accuracy across every clothing category, while meeting strict speed and cost constraints defined below.

Evaluation Criteria (Hard Requirements)

Criteria	Requirement
Accuracy	Best-in-class accuracy for EVERY clothing type tested (see list below) - correct garment fit, drap
Generation Time	Less than 15 seconds per generated try-on image
Cost per Generation	Less than Rs 4 per model/image generation
UI/UX	Visual polish is NOT a focus area - keep it bare-bones. Functionally, it must allow the user to (1
Primary Focus	Accuracy, Speed, and Model Optimization

Clothing Categories to Test

Every shortlisted model must be tested with try-on generations across each of the following categories (and any other common categories you identify as relevant):

- Saree
- Kurti
- Lehenga
- Top
- T-shirt
- Jumpsuit
- Coat
- Shirt
- Jeans
- Trousers

Required Functional Flow

- User uploads their own photo (the model/person image).
- User uploads a garment photo (the clothing item to try on).

- User selects the garment, and the system generates a visualization of that garment applied on the uploaded photo.

This flow is functional in nature only - do not spend time on visual design/styling of the interface. A minimal working script or bare interface that performs the above flow is sufficient.

Note on IDM-VTON Model

If you choose to use the IDM-VTON model, please note it has a known limitation: it does not give accurate results on saree and kurti garments out of the box. If you go with IDM-VTON, you are required to optimize the model (e.g. fine-tuning, pre/post-processing, prompt/parameter tuning, or other techniques) so that it gives acceptable accuracy on saree and kurti as well. If you are unable to achieve acceptable accuracy on these categories with IDM-VTON, please search for and evaluate other virtual try-on models instead.

What You Need to Do

- Research available virtual try-on models/APIs in the market (open-source and commercial).
- Shortlist models that can plausibly meet the accuracy, speed (under 15 sec), and cost (under Rs 4/generation) requirements.
- Test each shortlisted model across ALL clothing categories listed above using consistent model images and garment images.
- Record accuracy observations for each clothing type per model (fit, drape, texture fidelity, artifacts, face/body preservation).
- Record generation time and cost per generation for each test.
- Do NOT spend time on UI polish – a bare-bones test script/interface is sufficient. Focus all effort on evaluating accuracy, speed, and optimizing model settings/parameters.
- Make a proper screen recording showing the virtual try-on model working live during testing (across multiple clothing types).
- Upload the screen recording to Google Drive and set sharing access to 'Public / Anyone with the link'.
- Write a README file documenting the steps you followed, the model(s) you evaluated, configurations used, and your results/recommendation.

Cost Reimbursement

Any model/API usage cost incurred during testing will be reimbursed ONLY after the candidate is finally selected for the role. Please keep receipts/invoices or usage logs from the API providers for reimbursement processing at that stage.

Deliverables

- A shortlist/comparison of virtual try-on models tested, with accuracy, speed, and cost noted per clothing category.
- A screen recording (video) of the virtual try-on model working during testing, uploaded to Google Drive with public access enabled.
- A README file listing: steps followed, model(s) used, parameters/settings, and final recommendation.
- Final recommended model that satisfies: best accuracy across all clothing types, generation time under 15 sec, and cost under Rs 4 per generation.

Note: The focus of this assignment is model accuracy, generation speed, and optimization - not interface design. Please prioritize your time accordingly.
